neurological and muscle. We report a case of LGMD 2C associated with neuromusculardystrophy.

Case report.– A 15-year-old patient with a family history of LGMD 2C was presented with frontal headache patient, diplopia, bilateral ptosis. The physical examination revealed IIIrd and VIth cranial nerves palsies, a proximal myogenic syndrome with weak tendon reflexes. The electromyography detected abnormalities. Muscle biopsy showed lesions of dystrophy without sarcoid granuloma. The genetic study identified a MYOT deletion. FLAIR supratentorial showed periventricular hyper signals. The ankle equinus deformity was more common in the population of 5 to 10 years.

The ankle equinus deformity was more common in the population of 5 to 10 years. The study was retrospective, descriptive and analytical, and included 85 patients.

1985 and those born between 1985 and 1992. The study was retrospective, descriptive and analytical, and included 85 patients.

The ankle equinus deformity was more common in the population of 5 to 10 years. From 10 to 25 years, the knee flexion was the most frequent. The hip flexion deformity was the third most frequent. Scoliosis of more than 30° is the orthopedic deformity less raised in our population. The fusion of the spine (69% of patients) and tenotomy ankles (62% of patients) were the most identified orthopedic deformity less raised in our population. The fusion of the spine (69% of patients) and tenotomy ankles (62% of patients) were the most identified orthopedic deformity less raised in our population.

The cumulative incidence of ankles, knees and hips tenosynovitis were higher in the group of patients born after 1985. On the fusion of the spine, patients were operated later in the group born after 1985. We have not found any comparative data in the literature regarding the orthopedic evolution and the tenosynovitis. Anesthesiologists progress have probably delay the age of spine arthrodesis. There was surely a bias in the collection of scoliosis.

Our study has highlighted the evolution of DMD patients by orthopedic joint. It showed an increase in the incidence of tenosynovitis and achieving arthrodesis of the spine in a more advanced age. It would be interesting to compare these data with other centers. The study of functional surgery in DMD is to continue to maximize the indication and efficiency through the rehabilitation treatment.

Keywords: Polio; Epidemiology; Post polio syndrome

Introduction.– The 1950s marked the beginning of the epidemic in Algeria. The consequences of post polio from 25 to 40 years stability are late degradation is often multifactorial various physiological aging, medical and orthopedic complications, post-polio syndrome (30 to 65% of former polio are concerned). Polio was eradicated in Algeria, our concern is to provide an epidemiological approach to understanding the needs of care, and what is the reality of post polio syndrome.

Patients and methods.– A prospective cross-sectional study in 97 patients, chaff from 2010 to 2013 at the University Hospital of Sidi Bel Abbes and CHU Blida, Service MPR. Etude made statistical software SPSS 17.0.

Results.– Average age 40.
– Unusual academic grade level;
– patients with active (work) less than 35%;
– been made for a specific surgery polio less than 50%;
– paresis of the lower limbs, most answered;
– the majority of our patients were paired;
– a significant number of patients without any steps equipment joint or muscle pain is more common;
– the post-polio syndrome is present;
– the gene is the daily function of orthopedic disorders and also in post polio syndrome;
– the majority of our patients have one or more of these psychological symptoms: anxiety, depression.

Conclusion and discussion.– The population of surviving polio in Algeria still young, and the post polio syndrome is relatively frequent compared to the population in Europe: The application and care needs increase more in Algeria in this population, carrier effects of polio, orthopedic and functional gene and especially post polio syndrome.
A multicenter research in Algeria, particularly epidemiological need to learn more about the reality of this syndrome and the need for future care. http://dx.doi.org/10.1016/j.rehab.2013.07.547

P161-e Management of spinal muscular atrophy neuro-orthopedic complications: About three cases and review of literature
Service de médecine physique, rééducation et réadaptation fonctionnelle, CHU Fatouma Bourguiba, rue 1er Juin, 5000 Monastir, Tunisie

Keywords: Spinal muscular atrophy; Neuro-orthopedic complications

Introduction.– Typical childhood spinal muscular atrophy (SMA) is a disease that affects the anterior horn of the spinal cord related to SMN1 gene defects. Since no etiological treatment is currently available, its management is symptomatic and involves multidisciplinary care.

Case 1.– A 2-years-old girl presents a SMA type2 originally referred to hypotonia and confirmed by the genetic study. On examination, she has an axial hypotonia. She received regular physical rehabilitation, and instrumentation.
