**Objective** The objective of this study was to assess the functional and socio-professional future of lower limb-amputated patients.  

**Patients and methods** This is a 3-year-prospective study of lower limb-amputated patients, followed at the Physical Medicine and Rehabilitation department of the University Hospital of Monastir. The data analyzed were epidemiological, clinical, functional [the index of locomotion (ICL), the score “Special interest group of the amputee physician” (SIGAM)] and socio-professionals.  

**Results** We collected 101 patients with a mean age of 61.3 years with a male predominance (75.2%). Sixteen patients (15.8%) were initially braced and 58 (57.4%) had their device during the study period with an average delay of 10.08 months compared to surgery. Seventy-two patients had a job and only 8 amputees initially had a driving license. Forty-nine patients (48.5%) were initially able to do their own toilet against by 52 (51.5%) needing a third person to help them. After fitting, the rates have improved from 74.13% to 82.75 as well as the walking ability.  

For the device-fitted patients, ICL averaged 28.09. The average value of the non-ICL fitted patients initially increased from 25.89 to 31.25 (at least 6 months after being fitted). The SIGAM score assessment for all fitted patients showed that the most represented clinical grade was grade B for 20 patients (27.02%), followed by the degree F for 18 patients (24.32%). Forty-five patients (44.5%) had a professional outplacement and one remained able to drive after fitting.  

**Discussion/Conclusion** The device acquisition is a significant change for patients on the functional and professional levels. It allows a significant improvement in various activities of daily life with greater autonomy.

**Disclosure of interest** The authors declare that they have no competing interest.

**Objective** Evaluate the quality of life and psychological state of the lower limb amputees.  

**Patients and methods** Prospective study on the lower limb amputees followed at the Physical Medicine and Rehabilitation department of the University Hospital of Monastir. The variables analyzed were epidemiological, clinical with an assessment of the patients quality of life using the quality score of life “Short form 36” (SF36) and a psychological evaluation by the score “Hospital Anxiety and Depression scale” (HAD).  

**Results** Our population consisted of 101 patients, including 16 (15.8%) initially device-fitted and 58 (57.4%) who had their devices during the study period. The mean age was 61.3 years with a male predominance (75.2%). The vascular etiology of amputation was the most frequent (37.6%). The most represented level of amputation was transtibial (73.3%). The SF36 physical component score was initially more affected than the mental component with an average score of 32.53 PCS and MCS average 36.84. These scores were significantly higher among patients initially fitted. For 74 device-fitted patients, we observed a statistically significant improvement after device MCS scores ($P=0.001$) and PCS ($P=0.002$), as well as all the elementary scores of the SF-36 score. This improvement was slightly higher for the mental component. The HAD-A score was 9.28 with the presence of anxiety symptoms in 47 patients (46.6%). The HAD-D score was 10.26. Forty-five patients (44.5%) had depressive symptoms. For the fitted patients there was a statistically significant difference between the HAD-A scores ($P=0.002$) and HAD-D ($P<0.001$) from the initial psychological state and those after being fitted.

**Discussion/Conclusion** The impairment of quality of life, anxiety and depression are very common among amputees. The device allows a statistically significant improvement of the HAD and the physical and mental components of the SF-36.

**Disclosure of interest** The authors declare that they have no competing interest.

**Tunisian lower limb amputees and satisfaction lower towards their prostheses: About 74 cases**

Houda Migaou Miled*, Hichem Ben Brahim, Yafa Hadj Hassine, Soumaya Boudokhane, Nesrine Abdelkafi, Aymen Haj Salah, Sana Salah, Anis Jellad, Zohra Ben Salah Frih

**Objective** Assess satisfaction of lower limb amputees towards their device.

**Patients and methods** Prospective study of device-fitted lower limb amputees followed at the Physical Medicine and Rehabilitation department at the University Hospital of Monastir. Epidemiological and clinical parameters were assessed with evaluation of patients’ satisfaction towards their prosthesis (survey on the satisfaction of patients with lower limb amputations towards their prosthesis) (SAT-PRO).

**Results** We collected 74 lower limb amputees including 16 initially fitted and 58 who had their device during the study period. The average age of our patients was 62 years with a male predominance. The most frequent amputation level was transtibial (71%). The average delay of the device compared to the surgery was 10.08 months with extremes of 2–60 months. The age of the device for already fitted patients averaged 22.73 months with a range of 1–360 months. The calculated score of satisfaction towards the prosthesis (SAT-PRO) for fitted patients averaged 32.41 with extreme varying from 18 to 51. This assessment showed an improvement in the satisfaction of our prostheses patients. SAT-PRO means within this group was increased from 32.77 to 38.31 ($P=0.002$) with an average gain of 5.54±5.38. Satisfaction towards the prosthesis was positively correlated with the urban origin, high socioeconomic level, the age less than 65 years, the absence of disease history, the traumatic etiology, the level of distal amputation, the age of the device, the quality of life and the functional outcome score (ICL).

**Discussion/Conclusion** The level of satisfaction of lower limb amputees towards the prostheses depends on several factors. It is very important for its impact on the quality of life and autonomy.

Objective All recent studies confirm that the outcome of a conservative orthopaedic treatment depends on the compliance and the effectiveness of bracing measured by immediate in-brace curve correction. There is a correlation between immediate in-brace correction and biomechanical effectiveness of brace treatment in adolescent idiopathic scoliosis. In a retrospective analysis of the immediate in-brace correction obtained from a consecutive series of patients treated by the major SOSORT teams, the conclusion was that an effective brace should be able to achieve 50% correction of the curve magnitude, immediately after application.

The aim of this study is to provide a point of comparison between different braces and study the factors determining the reduction. Patients and methods/Study design This is a prospective controlled cohort observational study based on ongoing database including 544 patients with AIS treated with ARTbrace from May 2013 to November 2015. Only primary curves were selected, lumbar curves Lenke 5 are excluded as treated with the short GTB brace. The SRS criteria group consisted of 141 patients with 177 curves.

Results All 141 patients was reviewed at the control: no drop out.

The mean age was 12.92 years (SD = 1.39, range: 10–15). One hundred and twenty-five patients are female (88.7%).

The average initial Cobb angle was 29.62° (SD = 4.6, range: 25–40°).

The average in-brace correction (percent) was 72.5% (SD = 21.9, range: 29–140%).

At the thoracic level (n = 98).

The average initial Cobb angle was 30.33° (SD = 4.6, range: 25–40°).

The average in-brace Cobb angle was 10.04° (SD = 7.1, range: –12 to 29°).

The average in-brace correction (percent) was 67.6% (SD = 21.2, range: 29–140%), significant (P = 0.000).

At the thoracolumbar and lumbar for double major level (n = 75).

The average initial Cobb angle was 28.61° (SD = 4.1, range: 20–40°).

The average in-brace Cobb angle was 6.36° (SD = 6.5, range: –9 to 25°).

The average in-brace correction (percent) was 78.8% (SD = 21.3, range: 40–136%), significant (P = 0.000).

Discussion/Conclusion For the BrAIST study, average in-brace correction was 33% (n = 152, range: –48 to 100%).

The in-brace correction obtained by the asymmetrical high rigid polycarbonate detorsion brace corrects at least two times more than conventional polyethylene braces.

Creation of a brochure for amputees: Living with an amputation
Aurélie Vuilliez 1, *, François Luthi
Clinique Romande de Réadaptation, Appareil Locomoteur, Sion, Switzerland
* Corresponding author.
E-mail address: aurélie.vuilliez@crr-suva.ch (A. Vuilliez)

Objective A lower limb amputation is a major event for a patient with many questions arising for him and his family. Individual and environmental factors could influence patient’s quality of life and adaptation to amputation. Most of the time brochures concern post operative care after limb amputation (surgery type, stump medical care, prosthetics . . .). Rehabilitation is often only briefly dealt with these brochures.

Objectives of this study (1) To write a brochure specifically concerning rehabilitation for lower limb amputees. (2) To assess patients’ opinions and satisfaction concerning the relevance and quality of this brochure.

Material and methods (1) Creation of a multidisciplinary team. Creation of a brochure concerning rehabilitation. Modification after 5 amputees’ opinion (2 patients in rehabilitation and 3 after discharge).

(2) Brochure’s evaluation by lower limb amputees, living at home, with questions concerning: clarity, choice of themes selected and illustrations, reassurance, usability and utility. Open-ended and closed-ended questions.

Results (1) Illustrated brochure with 15 questions-and-answers concerning the following themes: “my preparation for active rehabilitation”, “recovering my autonomy” “return to everyday life”. Topics are: pain management, body image, physiotherapy, prosthetics, gait rehabilitation, driving adaptations, home adaptations, professional life, leisure and sports activities, place in society, insurances, illustrations by a cartoonist.

(2) Brochure sent to a hundred patients. Compilation of results ongoing.

Discussion/Conclusion An illustrated brochure concerning rehabilitation after an amputation was written and issued in digital format and in paper. Data recording is ongoing but the first findings are positive and very encouraging. This document including patients’ questions and professionals’ answers could form basis for discussion with patients and constitute a preliminary stage to a therapeutic education program.

Objective With cartilage physiopathology, knee stability and therefore the subsequent loadings on ligaments have a strong impact in the development of knee osteoarthritis. To understand this phenomenon, authors are proposing different knee models. Most of them are without any flexion, some have been introduced by controlling actively muscular groups. In this case, the forces used to achieve the flexion may not be physiological, and the pressure on the articulation can be questioned.
