Methods.— The study was carried out on 20 male Sprague-Dawley rats subdivided in 2 groups (G1: Healthy control, G2: model of pulmonary fibrosis induced by Bleomycine), using whole-body plethysmography and video recordings.

Results.— At rest, in G2, a decrease of expiratory time (TE) and total respiratory time (TTOT) was observed when compared to G1. The mean inspiratory flow (VT/TI) didn’t increase significantly in G2 when compared to G1 at rest. However during drinking, TE and VT/TI increased significantly in Fibrosis group. Swallowing frequency didn’t significantly change but the % of inspiratory swallowing (I) increased significantly when compared to G1.

Discussion.— Fibrosis can probably increase swallowing dysfunction and aspiration.

Aim of the study.— COPD is a major public health problem and a chronic systemic disease which decreases quality of life and effort capacity. Nevertheless rehabilitation programs decrease the number of exacerbations and hospitalizations. This explains why Physical Medicine and Rehabilitation plays a crucial role in COPD. Our aim was first to demonstrate that rehabilitation program increased functional parameters and quality of life and second to evaluate the place of neuromuscular electrical stimulation (NMES) of the quadriceps.

Material and methods.— Thirty two ambulatory patients (5F, age 58 ± 9 y) were included. Inclusion criteria were FEV1 ≤ 60% pred, FEF25/75 ≤ 70%, TLC ≥ 80% pred, dyspnea, 18 ≤ BMI < 35 kg/m², an optimized medical treatment, with or without O2 therapy or non invasive ventilation. COPD must be stable for one month.

All the patients performed pulmonary function tests, 6 minutes walking test (6MWT), incremental exercise test (VO2, maximal work rate WR) and Saint George’s quality of life questionnaire before and after eight weeks of rehabilitation program. At the onset of the program they were randomized to have quadriceps NMES at home (5 days a week, 30 min length, intensity 92°C) and maximal WR (66 ± 19 vs 73 ± 22 W, P = 0.001) increased. Saint George’s questionnaire total score showed a non-significant improvement (42 ± 11 vs 39 ± 13%). With additional quadriceps NMES, there was no difference in the improvement of the 6MWT distance, exercise tolerance and quality of life.

Discussion.— Our study demonstrated that rehabilitation program had a positive impact on functional parameters, with slightly improvement in quality of life of COPD patients. Nevertheless quadriceps NMES did not add a benefit in these ambulatory patients.

Keywords: COPD; 6-Minute Walk Test; Music

Introduction and aim.— The 6-Minute Walk Test (6MWT) evaluates the exercise tolerance and the functional capacity in patients with chronic obstructive pulmonary disease (COPD). Encouraging the patients during the test influences the walking distance. Moreover the music improves dyspnea in some conditions [1–2]. The aim of this study was to evaluate the effect of music with a fast tempo [3] on the distance walked during the 6MWT in COPD patients.

Method.— Eleven COPD patients (FEV1 = 39.1 ± 7.6% of predicted values) performed randomly the same day a walking test in two different conditions: without music (WM) and with a fast music (FM). The 6MWD, the cardio-respiratory parameters and the dyspnea were measured.

Results.— No difference was observed on the walking distance depending on the conditions (WM: 350 m – FM: 366 m, P = 0.101). Cardio-respiratory parameters and dyspnea were not influenced by the music.

Discussion and conclusion.— In this preliminary study, music with a fast tempo did not modify the results of the 6MWT.

Mots clés : Revalidation pulmonaire ; Dyspnée ; Fatigue ; Musique

Introduction et objectif.— La revalidation pulmonaire fait partie intégrante de la prise en charge des patients atteints de broncho-pneumopathies chroniques obstructives (BPCO). Le maintien de la participation des patients BPCO à un programme de revalidation est un challenge pour l’équipe soignante. La musique a montré des effets bénéfiques sur différents paramètres impliqués dans la réduction de la perception de la fatigue chez des patients BPCO pendant une séance de revalidation pulmonaire.

Matériel et méthode.— De manière aléatoire, les patients BPCO et participant à un programme de revalidation pulmonaire ont été soumis à des séances de revalidation séparées. Les patients évaluent le niveau de perception de la fatigue. Afin de déterminer l’influence de la musique sur l’effort nécessaire à la réalisation d’une séance de revalidation, les patients ont effectué le 6-Minute Walk Test (6MWT) dans deux conditions: sans musique et avec le temps de la musique alloué au 6MWT. Les paramètres cardio-respiratoires et la dyspnée ont été mesurés et comparés.

Résultats.— Trente-et-un paires de séances ont été comparées. Les caractéristiques des patients (moyennes ± DS) étaient un âge de 70,5 ± 8,4 ans, un BMI de
