The Currarino syndrome is a rare trouble, which contains three distinct diseases: a partial sacral agenesis, a presacral mass and an anorectal malformation. In our patient, the revelation came lately due to a complication of a myelomeningocele, then the appearance of arachnoid cysts after a meningal infection.

**Observation.**– We report the case of a 29-year-old woman who presented suddenly paraplegia in a context of a meningal infection. The initial intervention as a matter of urgency on a myelomeningocele and a fistula communicating between the spinal canal and perianal area has solved the problem of infection. The patient is afterwards transferred to for rehabilitation medicine. In front of sphincters disorders, urodynamic check-up find data which does not match with the lesional level. Arachnoid cysts were identified, and were released surgically. Thereafter, an intensive rehabilitation was undertaken and it has permitted a neurologically and functionally improvement. The better testing of lower limbs was noticed during the hospitalisation. Moreover, an effective walking has been possible after 9 months of daily functional work, stimulation and muscular strengthening.

**Discussion.**– This case reveals the effectiveness of an intensive rehabilitation program following an arachnoid cysts surgery. The motive recovery allowed the resumption of orthostatism after 7 months and the walk with technical helps at 9 months in a patient who had a total paraplegia before surgery. The literature emphasises the idea to suggest an intensive rehabilitation treatment following this type of surgery. Certain kind of fast improvement was described for reduced-time spinal pains. But, according to the description of some teams, in the case of late operation, the rehabilitation is essential to hope an improvement. If that aggravates, it is necessary to control again the imagery to uncover a recurrence of cysts.

**Keywords:** Sigmoid colon; Volvulus; Spinal cord injury

**Introduction.**– Gastrointestinal dysfunction is a major cause of morbidity among individuals with spinal cord injury (SCI). Chronic complications such as obstruction and fecal incontinence are common. Intermittent sigmoid volvulus (SV) is a rare complication in SCI patients. We report a case and review the literature on SV in SCI patients.

**Observations.**– A 54-year-old man with a traumatic SCI T12 AIS D in 2000 and L3 fracture in 2011, presented with a history of abdominal discomfort since a couple of months. Abdominal X-ray showed a distended colon descendents with an inverted U shape, consistent with SV. A diagnosis of an uncomplicated SV was established. Because of minor complaints the patient was given a low dose osmotic laxative to improve bowel transit. Four months later the patient showed persistent complaints of constipation alternating with diarrhea. A surgical reduction of the volvulus was planned. Initially, a laparoscopic approach was performed, but massive bowel distension and anatomical distortion hampered adequate view. Conversion to laparotomy was done and a sigmoid resection was performed.

**Discussion.**– Following this case we performed a literature review on spontaneous SV and SV associated with SCI. Only one article on SV in association with SCI was retrieved describing a series of 8 patients (Fenton-Lee, 1993). The understanding of SV has improved over the years. Etiology of SV is unclear but is thought to be multifactorial. Immobility, prolonged colonic transit time and constipation may be predisposing factors. In general, the sigmoid colon is the most common location of volvulus. Although spontaneous reduction have been shown to occur in about 2% of patients, conservative management in the hope that volvulus will reduce spontaneously, is not recommended. Emergency endoscopic reduction is the treatment of choice for acute volvulus, but satisfying clinical result is mostly temporary. A sigmoid resection is advised as a definitive solution.

In case of persisting constipation in patients with SCI an abdominal X-ray should be performed in order to diagnose a possible volvulus that may present more silently, as this may have therapeutic consequences.
